In-Transit Material Tracking

To track the movement of material between warehouses or between accounting entities, the Info.Net system will always create two transactions; the first recording the issued of material from the first warehouse and the second transaction recording the receipt of material to the second warehouse.

If a transfer of material is to take some time, and in-transit tracking is required, the material will be transferred from the first warehouse to an in-transit location (of which, any number can be created). Each in-transit location has its own unique inventory account and the location of the in-transit material will show in inventory queries and reports as being located in the specified in-transit location.

The receiving warehouse can then create a second transaction, basically transferring the material from the in-transit location into their warehouse, completing the transfer.
