

Multiple Time Phased Pricing Tables

The Info.Net contains two types of sales order item pricing algorithms. The first type includes pricing algorithms based on the following:

- Product class within customer
- Customer
- Part number / Marketing model
- Customer class
- Product class

These pricing types can be defined as an amount off or a discount percentage off of a product list price or the pricing type can directly specify the item price. Associated with the pricing algorithm is an optional volume pricing definition.

The second type of pricing is based on additional charges added to an item's standard cost. Any number of pricing types can be created which define percentage increases or specific values added to the items standard cost, or percentage based increases can be added to an items final price.

Any number of this second type of sales price can be created for a saleable part number.
