Standard Yield Costing

If a manufacturing environment contains defined yields at one or more routing operations, the Info.Net system can define the yield at each relevant operation within a routing, and the standard cost rollup will use these individual operational yields when calculating the standard cost of an assembly.

The user defined planned yield entries will be converted into a standard yield through the standard cost update routines and will subsequently be used in determining the quantity of material required during the MRP planning process and in calculating work in process material and labor requirements.
